### Abstract

Plant-derived foods rich in polyphenols are associated with several cardiometabolic health benefits, such as reduced postprandial hyperglycaemia. However, their impact on whole-body insulin sensitivity using the hyperinsulinaemic-euglycaemic clamp technique remains under-studied. We aimed to determine the effects of strawberry and cranberry polyphenols (SCP) on insulin sensitivity, glucose tolerance, insulin secretion, lipid profile, inflammation and oxidative stress markers in free-living insulin-resistant overweight or obese human subjects (*n* 41) in a parallel, double-blind, controlled and randomised clinical trial. The experimental group consumed an SCP beverage (333 mg SCP) daily for 6 weeks, whereas the Control group received a flavour-matched Control beverage that contained 0 mg SCP. At the beginning and at the end of the experimental period, insulin sensitivity was assessed by a hyperinsulinaemic-euglycaemic clamp, and glucose tolerance and insulin secretion by a 2-h oral glucose tolerance test (OGTT). Insulin sensitivity increased in the SCP group as compared with the Control group ( $+0.9$  (SEM 0.5)  $\times 10^{-3}$  v.  $-0.5$  (SEM 0.5)  $\times 10^{-3}$  mg/kg per min per pmol, respectively,  $P=0.03$ ). Compared with the Control group, the SCP group had a lower first-phase insulin secretion response as measured by C-peptide levels during the first 30 min of the OGTT ( $P=0.002$ ). No differences were detected between the two groups for lipids and markers of inflammation and oxidative stress. A 6-week dietary intervention with 333 mg of polyphenols from strawberries and cranberries improved insulin sensitivity in overweight and obese non-diabetic, insulin-resistant human subjects but was not effective in improving other cardiometabolic risk factors.

**Key words:** Polyphenols: Strawberries: Cranberries: Insulin sensitivity: Glucose metabolism: Insulin secretion: Insulin-resistant subjects

According to the International Diabetes Federation<sup>(1)</sup>, up to 592 million people worldwide (one in ten adults) will suffer from type 2 diabetes by the year 2035. This alarming increase has been predicted based on several factors, such as the high prevalence of obesity and sedentary lifestyles<sup>(2,3)</sup>. Indeed in obese humans, elevated levels of NEFA, pro-inflammatory cytokines and other factors produced by adipose tissue are key determinants of insulin resistance<sup>(4)</sup>. To maintain plasma glucose at normal levels, pancreatic  $\beta$ -cells must adjust their function to compensate for insulin resistance. This leads to an exhaustion of  $\beta$ -cell insulin secretion and the development of impaired glucose tolerance (IGT) and subsequent type 2 diabetes.

In recent decades, scientific evidence has shown a link between increased consumption of fruits and vegetables, particularly berries,

and reduced incidence of type 2 diabetes<sup>(5)</sup>. Recent reviews have indeed reported that berries, like strawberries and cranberries, can lower markers of cardiometabolic risk<sup>(6–11)</sup> and improve markers of the metabolic syndrome in humans<sup>(12–14)</sup>. It is well-documented that strawberries and cranberries are rich in polyphenols and contain a wide variety of phenolic compounds, ranging from phenolic acids (hydroxybenzoic and hydroxycinnamic acids), flavonoids (anthocyanins, flavonols and flavan-3-ols) to polymerised molecules (proanthocyanidins and ellagitannins)<sup>(15)</sup>. According to several *in vitro* and animal studies, polyphenols may improve glucose metabolism<sup>(16)</sup> and peripheral glucose uptake in insulin-sensitive tissues by increasing GLUT4 translocation and activity and reducing oxidative stress and inflammation<sup>(17,18)</sup>. It has recently been demonstrated that anthocyanin-rich bilberry

**Abbreviations:** IAUC, incremental AUC; IGT, impaired glucose tolerance; *M/I*, insulin sensitivity index; OGTT, oral glucose tolerance test; SCP, strawberry and cranberry polyphenols; UHPLC, ultra-high performance liquid chromatography (UHPLC).
